APPENDIX B

Dolomite Panel Cleaning Study and Reuse Feasibility Analysis

Simpson Gumpertz & Heger Inc.
Consulting Engineers

Arlington, MA / San Francisco, CA

BY FAX AND U.S. MAIL

10 March 2000

Ms. Deborah A. Boyer
Director of Operations & Construction
Kaiser Center, Inc.
300 Lakeside Dr., Suite 130
Oakland, California 94612-3534

Comm. 98843.01 — Construction Administration, Concrete Wall Repairs, Kaiser Center,
Oakland, CA

Dear Ms. Boyer:

This letter is in response to your request for maintenance guidelines of the rehabilitation work performed by Western Waterproofing at the above referenced project. Western Waterproofing's rehabilitation scope included sealant replacement, concrete spall repair, sealing concrete panels, and aluminum coping installation. The maintenance guidelines for each of these items are listed below.

Sealant

In accordance with the manufacturers recommendations, the Sikaflex 2c replacement sealant should be visually inspected every five years to check the performance of the sealant. The Sikaflex 2c normally will not require repair or replacement for at least ten years dependent on exposure. If a failure is observed, that portion of the sealant joint should be removed and the surface of the panels should be cleaned and free of foreign materials that would inhibit bonding. The sealant should then be replaced with Sikaflex 2c using a joint width-to-depth ratio of 2 to 1 using new backing material to set the joint depth. We recommend that a qualified waterproofing contractor perform any sealant repairs to assure that the joints are prepared properly.

Concrete Spall Repairs

The exposed aggregate panels should be monitored for further spalling. If additional spalls should occur, the spalls should be removed, and the area prepared and repaired according to the specifications. The spalls should be repaired by a company with experience in restoration and concrete patching.

Note that the final mix design included one part lime, one part grey Portland Type II cement and two parts sand. This mix was developed as part of the submittal process and is not in the specifications.

Concrete Sealer

The Dynasylan BH-N clear penetrating sealer is a surfaced-applied sealer which affects the top 1/2 inch of the wall surface. The sealer is colorless and therefore it is impossible to determine the condition of the sealer over time by visual observation. The condition of the sealer can only be assessed by coring the wall and doing a chemical analysis of the surface. For maintenance, the manufacturer suggests recoating the wall in 10 to 15 years. This product is affected by environmental exposure so the condition of the sealer on the three facades may vary by the time of resealing. Prior to resealing, it is prudent to conduct an inconspicuous mock-up on each facade to determine any negative aesthetic results, such as darkening. Concrete coating and sealing technology changes constantly. We would recommend consulting product representatives of Dynasylan or other consultants for an evaluation of then current products and compatibility with the Dynasylan BH-N.

Aluminum Coping

The aluminum coping extension should be checked biyearly from the roof to verify the condition of the sealants used at the metal joints. Because of its exposure to weather, the coping seals experience a lot of movement. If a failure is observed, that portion of the sealant joint should be removed and the surface of the panels should be cleaned and free of foreign materials that would inhibit bonding. The sealant should then be replaced with Sikaflex 2c using a bond breaker at the fillet-type joints. We recommend that a qualified waterproofing contractor perform any sealant repairs to assure that the joints are prepared properly.

Conclusion

The above guidelines are meant to assist you in maintaining your property. A periodic inspection of every five years should help Kaiser Center monitor the performance of exterior concrete walls. There are many factors which affect the performance of the exterior cladding materials, especially environmental factors, such as sun, wind, rain and airborne contaminants. Therefore, the various products will require repair or replacement at different times. Any failures within the warranty periods, however, should be brought to Western Waterproofing and Simpson Gumpertz & Heger's attention.

We hope this letter assists you in the long-term maintenance of your building. If you have any questions or concerns, please do not hesitate to call.

Sincerely yours,

Jonathan T. Stafford, Engineer
I:\COMMISS\1998\98800\98843\01KCAL16JTS99.WPD

Encl.

cc: Mr. Robert P. Browne, Western Waterproofing (w/o encl.)

Sikaflex®-2c Maintenance Procedure

1) Preconditions:

- a) As a premium-grade two component polyurethane elastomeric joint sealant Sikaflex-2c is suitable for sealing properly designed working joints. The self-leveling grade for horizontal joints and the non-sag consistency for vertical and overhead joints.
- b) Sikaflex-2c is normally applied at a minimum thickness of 1/4 inch by use of a bulk gun or by manually pouring the self-leveling grade.
- c) Sikaflex-2c is normally used to seal joints between concrete, masonry, aluminum or coated metal panels and EIFS systems that have been suitably prepared, repaired or conditioned in accordance with Sika's current technical data sheets.

2) Maintenance Procedure:

These maintenance recommendations given below relate to the product correctly applied in accordance with the preconditions above.

In accordance with standard good practices all sealant systems, including Sikaflex-2c, should at least be visually inspected every 5 years. Sikaflex-2c will normally not require maintenance (i.e. resealing) for at least 10 years dependent on exposure. When eventual maintenance is required, the following procedure should be closely observed:

- a) Cut out all damaged sealant with a manual or mechanical device. By mechanical means remove all other foreign or deleterious materials that might prevent bond.
- b) When the substrate is clean, sound and dry, reapply the sealant in accordance with the original Sikaflex-2c specification.
- c) The sealant shall be applied with a minimal thickness of 1/4 inch and in the industry acceptable ratio, width to depth, of 2:1. Note that a 1:1 ratio is also tolerable in various situations.

- d) Allow the sealant to cure normally and plan the next visual inspection in 5 years and possible routine maintenance in 10-15 years dependent on exposure and requirements.

3) Warranties:

Subject to satisfactory compliance with all of the above, Sika Corporation will issue a further warranty for this system in accordance with our standard policies.

Comm. 98843.00 — Exterior Wall Cleaning and Coating Study, Kaiser Center, Oakland, CA

Dear Deborah:

Introduction

At your request, Simpson Gumpertz & Heger Inc. (SGH) has conducted an investigation of methods to clean and repair the exterior walls at the Kaiser Center. The Kaiser Center is a 28-story office building (Photo 1), built in the early 1960's, located in Oakland, California. Most of the exterior wall is an aluminum and glass curtain wall. Solid stair tower walls are clad in precast concrete with exposed dolomite aggregate finish.

You identified two problems for us to investigate:

1. The aluminum curtain wall panels are dirty and unsightly.
2. The concrete walls are streaked and dirty.

Our work to date has consisted of a review of original construction documents, visual surveys of the exterior walls, close-up inspections from swing stages, laboratory analysis of samples, cleaning test mock-ups, recommendations for cleaning and repair, and an estimate of probable construction cost.

Information Obtained From Others

We reviewed the original drawings and specifications, by architect Welton Becket & Associates and found the following pertinent information:

- Four types of finishes were used on the aluminum (Sheet 1008, dated 1-29-58):
 - Column covers are a dark grey color identified as "material: .125#7BP with finish C1-A2."
 - Beam fascias are a light grey color identified as "material: 6063-T5 with finish C1-A2."
 - Mullions are a light grey color identified as "material: 6063-T5 with finish C1-A2."
 - Spandrel panels are a gold color identified as "material: 125 gold alloy, ribs embossed vertically, with finish C1-A2."
- Precast concrete panels are lightweight concrete with a decorative dolomite aggregate finish. (Specification Section XIII)

We interviewed personnel familiar with the building:

- According to the building engineer, George, pieces of concrete have spalled from the panels since shortly after construction. A small, tan colored aggregate particle is at the apex of the spalls, and appears to be the point of origin of the spalls. The concrete was coated with an epoxy sealer to prevent water from reaching the aggregate particle and causing expansion of the particle and spalling. There have been fewer spalls since the sealer was applied.
- According to Dick Schroter of SGH, who worked for Kaiser at the time of construction, the aggregate causing the spalls was reported to be burnt dolomite, which was transported in the same trucks as the exposed aggregate dolomite. The burnt dolomite became mixed into the aggregate for the precast panels, and caused the spalls.

We reviewed two letter reports by Western Restoration, dated 23 September 1991 and 24 October 1991, regarding exterior cleaning.

- Western Restoration conducted cleaning tests on the north concrete wall at ground level, using various chemical cleaners manufactured by ProSoCo. They recommended a cleaning program consisting of:
 - a. Water blast
 - b. Apply poultice and allow to dwell for 24 hours
 - c. Remove poultice
 - d. Pressure wash
 - e. Apply ProSoCo limestone restorer
 - f. Apply ProSoCo Weather Seal Siloxane

Steps a, d and e would have to be done after hours, and the poultice removed in step c would have to be disposed of as hazardous waste.

- Western Restoration recommended cleaning the aluminum with Sure Klean Aluminum Cleaner.

Field Observations

Carolyn Searls made a visual survey of the entire building from street level and a close up survey of the lower portion of the north concrete wall on 18 July 1998:

Concrete Walls

All concrete walls are streaked and dirty. The epoxy sealer is cracked and brittle. It has worn off in some areas but is intact in other areas. There are incipient spalls and previously patched spalls visible on all concrete walls. The concrete panels are dirtier on the tower than at the lower podium.

North Wall

We accessed the north wall up to the fourth floor using a lift. We removed two incipient spalls from the concrete panels. A tan-colored aggregate particle was found at the base of each spall. The particles were cracked and disintegrating. In the area up to the sixth floor we could see five other incipient spalls and 17 previously patched spalls (Photo 2).

Aluminum and Glass Curtain Wall

The aluminum is dirtier at the north and east sides of the building (Photo 3). The louvers near the top of the building appear especially dirty. The aluminum on the south side of the podium has been scuffed and scratched (Photo 4).

We made further inspections on 27 August 1998.

East Concrete Wall

Carolyn Searls and George (the building engineer) made a close up inspection of the east concrete wall on 27 August 1998. The swing stage covered the south half of the wall only. We made the following observations:

- We identified and removed 31 incipient spalls. Photo 5 shows a typical spall. Most of the spalls were easy to remove by hand or with a little prying with a screwdriver.
- We saw many incipient spalls at the half of the wall we could not reach from our swing stage. (Photo 6)
- We saw one area where concrete had recently spalled. (The concrete where the spall had been was still clean.) (Photo 7)
- The spalls range in size from 2 in. to 9 in. in diameter, and ½ in. to 1-3/4 in. deep.
- Most spalls have one tan, disintegrating aggregate particle at the apex of the spall. One spall has two particles.
- While on the wall, we noticed that the sealant is in fairly good condition with some small areas of adhesive failure. The sealant is still fairly elastic. It is placed over a fibrous backer rod.
- The epoxy sealer is worn off the dolomite aggregate, but remains on some of the cement paste between the aggregate. It is brittle and flaky.
- The metal roof coping does not cover the top of the precast panels, leaving the top horizontal concrete surface exposed. (Photo 8)
- The ends of steel rods are sticking out at the 26th and 27th floors. These rods may have originally been installed to support the "Kaiser Center" sign shown on the drawings. The sign is no longer in place on this elevation.

Aluminum and Glass Curtain Wall

Carolyn Searls observed the aluminum curtain wall close up at the fourth floor roof and from a swing stage on the east elevation, and made the following observations:

- All aluminum elements are dirty. The ribbed gold panels are more dirty than the smooth grey column covers and mullions.
- Some gold panels have patches of oxidation product, as shown in Photo 9. If the oxidation product is scraped off, a pit in the aluminum remains.
- The pitting on the drop we surveyed was worse at about the mid height of the building.

Field Tests

Aluminum Cleaning

On 15 September 1998, AMS Architectural Technologies Inc. performed mock-ups of the cleaning of the aluminum. The first mock-up is located at the 17th floor, south elevation, between Column Lines 7 and 8. We selected this panel for the mock up because it was representative of the most severe corrosion and pitting we saw. The gold, ribbed panel was cleaned. Before cleaning the aluminum was dirty and had irregular shaped spots of oxidation products from corrosion of the aluminum, as shown in Photo 9.

AMS cleaned the panel by hand scrubbing with nylon abrasive pads and detergent. After rinsing and drying, they applied a surface protectant.

After cleaning, some dirt remained in the grooves, but the panel was fairly and uniformly clean. We could see the pits in the aluminum from the swing stage (Photo 10), but not from the street. The cleaned panel is much cleaner than the adjacent panels and is readily visible from the street (Photo 11).

AMS cleaned a second mock up at the fourth floor roof level, north elevation, at the east end of the building, as shown in Photo 12:

- Gold ribbed panels: AMS cleaned two gold panels — one especially pitted and one heavily soiled panel. After cleaning and applying the surface protectant, the pitting is still visible. Both panels are uniformly clean except at a strip at the lower 2 in. of the panels. It was difficult to clean this area because of interference from the horizontal mullion below the panel.
- Light grey spandrels and mullions: AMS found that these elements have a lacquer coating. They removed the lacquer, cleaned the panels and applied the surface protectant. The panels are visibly cleaner than the adjacent uncleaned areas.
- Dark grey column covers: These elements also have a lacquer coating. AMS removed the lacquer and cleaned the panels. The cleaned panels are visibly cleaner than the adjacent uncleaned areas.

On 12 December 1998, Stuart Dean Co, Inc. performed a mock up of the cleaning of the aluminum on the fourth floor roof level on the north elevation of the building. The cleaning included two gold ribbed panels, two light grey horizontal mullions and a six foot section of the dark grey column covers.

The panels were cleaned using 3M nylon pads and a liquid detergent. The gold ribbed panels had to be cleaned using an additional lacquer stripper in order to remove the shipping coating. After the cleaning, the panels were allowed to dry and were then sealed with a surface protectant.

Before cleaning the panels were very dirty, showed signs of pitting and oxidization, and were scratched in places, assumed to be caused by the window washing equipment.

After cleaning the panels were fairly clean with minimal dirt remaining on the surface. The pitting on the surface and scratches from the window washers equipment were still visible. The cleaned panels stood out against the dirty panels around them.

Concrete Cleaning

On 13 October 1998, Western Waterproofing and JOS/Quintek performed cleaning mock ups of the concrete panels. The mock-ups are located at ground level on the north side of the building. Four cleaning methods were tried:

- JOS System. This system uses a microabrasive fine dolomite powder mixed with water applied at low pressures. The process was not successful in removing the epoxy coating, and was extremely messy, requiring large amounts of the microabrasive. This system is not recommended.
- Black Beauty: This is a dry blast method. It damaged the dolomite aggregate and is not recommended.
- Rotec steam cleaning. The Rotec system uses steam projected in a flat fan spray (Photo 13). A variety of pressures from 1000 psi to 3000 psi, with a small and large nozzle were tested. The 3000 psi pressure using the small nozzle was most effective (Photo 14).
- Rotec steam cleaning with polymer cracker. A chemical "polymer cracker" was brushed on the concrete and allowed to dwell for 6 ½ hours. It was then removed with the steam cleaning at 2500 psi. The improvement over the steam cleaning alone was marginal.

We observed further cleaning tests conducted by Western Waterproofing on 14 January 1999. They tested:

- Peel Away 7 paint stripper, dwell time 1-1/2 hours, removed with a power wash.
- High pressure cold water power wash.

Neither of the techniques was as effective as the Rotec steam cleaning.

Laboratory Tests

We performed a microscopic examination of two spalls removed from the concrete and x-ray diffraction analysis of the tan aggregate particles found at the apex of the spalls. The complete report is attached, and our findings are summarized herein. The spalls are caused by fragments of burnt dolomite within the concrete which experience up to a 200% increase in volume when exposed to moisture over long periods. When the burnt dolomite expands, it fractures the surrounding concrete, creating the spalls. The previously applied coating has trapped moisture behind the outer surface of the concrete and probably exacerbated the spalling.

Unreacted aggregate particles are still present in the concrete; therefore, the spalling can be expected to continue as long as a source of moisture is provided. However, the concrete provides some restraint of expanding particles, and spalls only occur to a certain depth. At some time, all shallow particles will have expanded and spalled, and the spalling will stop. Determining the number of spalls on the building over several years is the best method of determining if the spalls have slowed or stopped.

We had Sivento, Inc., a manufacturer of water repellents, perform tests of the efficacy of water repellent coating for the concrete. The complete report is attached, and our findings are summarized herein.

We submitted two steam-cleaned concrete spalls (which we had removed from the east wall) to Sivento for testing. Sivento coated one sample with their Dynasytan BH-N water repellent and measured the 24-hour water absorption of the treated sample and one untreated sample. The untreated sample absorption was 0.90%, and the treated sample absorption was 0.24%.

Both treated and untreated samples have low water absorption. The moisture causing the spalls may be caused more by the water trapped by the epoxy coating than by absorption through the surface of the concrete. Further testing would be required to determine the primary source of the moisture and how effective a water repellent will be. However, a breathable water repellent (such as Dynasytan BH-N) will not cause any harm and could reduce the spalling.

Recommendations

We recommend the following repairs:

Aluminum Curtain Wall

1. Clean the aluminum surfaces using mild cleaners, hand scrubbing and water rinse.
2. Seal aluminum surfaces with either AMS #350 or Stuart Dean's Sodric sealers.

The following table compares the proposals submitted thus far by AMS and Stuart Dean. We have worked with both contractors, and we believe either one is capable of performing this work.

Comparison of Aluminum Cleaning Proposals		
Category	AMS	Stuart Dean
Price	\$698,323.84, including staging	\$750,000 \pm 10%, including staging*
Cleaning	Hand scrub, water rinse	Hand scrub, water rinse
Sealing	AMS #350 0.1 mil thickness siloxane	Sodric 1.0 mil thickness acrylic-silicone blend
Maintenance: Washing	once/year with water	once/year with water
Maintenance: Resealing	3 years or more, depending on exposure, likely 5 years	3 years or more, depending on exposure, likely 5 years

Comparison of Aluminum Cleaning Proposals		
Category	AMS	Stuart Dean
Duration	Within 1 year, flexible to meet needs of owner	Within 1 year, flexible to meet needs of owner
Guarantee	3 years	3 years

*Stuart Dean has requested to be allowed to perform do another test panel (time and motion study) similar to that done by AMS, in order to finalize their price

Concrete Walls

1. Clean the concrete using the Rotec steam cleaning method.
2. Remove incipient spalls.
3. Patch spalls with mortar. Embed dolomite aggregate in the patch to match the existing surface.
4. Apply Dynasylan BH-N water repellant.
5. Install sheet metal coping at the top of the concrete walls to reduce water infiltration into the concrete panels.

Our specifications require the contractor to install a sample panel showing all of the repairs, to verify acceptable appearance of, and to set a standard for the rest of the work.

Cost Estimate

We have prepared the following cost estimate for your budgeting purposes:

Item	Cost	Estimate by
Aluminum Curtain Wall		
Cleaning and Sealing (incl. staging)	\$698,324	AMS
Concrete Walls		
Cleaning (incl. staging)	\$245,000	Western Waterproofing
Water repellant	85,000	Western Waterproofing
Coping	4,450	Western Waterproofing
Spall patching	25,000	Western Waterproofing
Total Concrete Walls	\$359,450	

Item	Cost	Estimate by
Engineering Fees		
Construction documents	\$15,000	SGH
Construction administration	40,000	SGH
Total Engineering Fees	\$55,000	
GRAND TOTAL	\$1,112,774	

Once you have received approval to proceed, we will prepare construction documents for the work. We will need input from you concerning your requirements for the owner/contractor agreement, as well as special requirements for working hours, noise, etc. We will submit the construction documents to AMS, Stuart Dean, and Western Waterproofing for bidding. We are available to provide construction observation during the work.

Sincerely yours,

Carolyn L. Searls, Senior Associate, VP

APPENDIX A

MICROSCOPIC EXAMINATION AND ANALYSIS OF HARDENED CONCRETE

Simpson Gumpertz & Heger Inc.
Consulting Engineers

Arlington, MA / San Francisco, CA

M E M O R A N D U M

Date: 2 October 1998

To: Carolyn Searls and File

From: Mauro J. Scali, Staff Consultant/Petrography

Comm. 98843 – Investigation of Precast Concrete Panel Failures – Kaiser Building,
San Francisco, CA

Subject: Microscopic Examination and Analysis of Hardened Concrete

Per your request, we have completed a microscopic examination and analysis of hardened concrete samples from the Kaiser Building, located in San Francisco, California. The purpose of the laboratory testing is to determine the underlying cause of popouts in the exposed surfaces of the precast concrete panels on the exterior of the building.

This memorandum provides a summary of the results of the visual and microscopic examination and x-ray diffraction analysis of the submitted test samples.

Sample Description

The test samples consist of two small, irregular, conically-shaped fractured spalled sections of hardened concrete. The test samples were removed from two different precast panels on the exterior of the building. The test samples were identified as ES -1 and ES -2, with nominal dimensions 6X8 in. and 6-1/2 X 9-1/2 in., respectively.

Sample Preparation

Each sample was cut transversely to expose a cross-section of the hardened concrete. The cut sections were then lapped and ground smooth to create planar, polished surfaces for conducting a microscopic examination of the precast concrete. In addition, a portion of each sample was submitted for preparation of ultra-thin (23 μ m -27 μ m, about 0.0009 in. to 0.001 in. thick) sections that were used to conduct a more detailed examination and analysis of the aggregate and surrounding paste structure.

A portion of Sample ES -1 containing a fragment of a tan color aggregate was submitted to an independent testing laboratory for x-ray diffraction (XRD) analysis. The sample was selected on the basis of the location of the aggregate near the center of the fractured concrete surface.

Microscopic Examination

Using both visual and microscopic techniques, portions of prepared and unprepared surfaces of each sample, including ultra-thin sections, were examined in accordance with selected portions of ASTM C856 "Petrographic Examination of Hardened Concrete."

Polished and fractured sections from each sample were examined with the aid of a stereo microscope at magnifications of 10X to 100X. In addition, a more detailed examination of the prepared thin sections was conducted with the aid of a transmitted-light polarizing microscope, at magnifications of 50X to 800X.

Test Results

Visual and Microscopic Examination

The results of our visual and microscopic examination are summarized below:

- Both samples exhibit a conical cross-section having a maximum thickness of 1-1/4 in. In both instances, there are multiple pieces of small (1/8 to 1/4 in.), tan to brown color aggregate located at the apex or along the crest of the conical spall fracture (Figures 1 and 2).
- The small tan color particles are soft and easily disrupted when probed with a steel pick.
- The exterior surface of the concrete is dark with light color splotches (Figure 3). The dark color is due to a yellowed, translucent polymer coating on the exterior surface of the concrete. The surface coating exhibits extensive cracking and has pulled away from the surfaces of exposed aggregate particles creating the contrasting light color splotches (Figure 4).
- In general, the surface coating is well bonded to the concrete, except where it has curled and pulled away from the coarse aggregate particles (Figure 5).
- The coarse aggregate consists of 3/4 to 1 in. maximum sized particles of white marble, which are present throughout the full depth of the spalled concrete.
- There is microcracking and evidence of expansion fractures in the tan color aggregate particles (Figure 6).

X-Ray Diffraction (XRD) Analysis

The results of the XRD analysis are summarized below and a copy of the x-ray spectra is included as an attachment to this report. The x-ray diffraction analysis identified the following phases in the tan color particles.

- MgO
- Ca(OH)_2
- Calcite (CaCO_3)
- Brucite [Mg(OH)_2]
- Hematite (Fe_2O_3)
- Aragonite (CaCO_3), small amounts
- Dolomite [$\text{CaMg(CO}_3)_2$], small amounts

Based on the presence of the above compounds and mineral species, the following chemical reactions are believed to have occurred when the tan color particles were exposed to moisture:

Both of these reactions can result in as much as a 200% increase in the volume of the aggregate.

Subsequently, the calcium hydroxide combines with air and water-borne carbon dioxide (CO_2) to form the calcium carbonate that was detected in the tan color particles. The CaO reaction is much more rapid and more likely to have gone to completion as compared to the MgO reaction. Therefore, it is not surprising that CaO (lime) was not detected by XRD analysis of the already expanded tan color aggregate.

Summary and Conclusions

Based on all of the test results, it is concluded that the surface popouts are due to the presence of a contaminant within the concrete, which is expansive in the presence moisture.

The XRD analysis detected calcium carbonate and brucite that were formed from lime (CaO) and magnesium oxide (MgO) in the original aggregate. The tan color aggregate also contains small amounts of dolomite and Aragonite.

The presence of dolomite and Aragonite indicate that the tan color fragments were originally formed from a dolomitic rock. Furthermore, the small quantities of dolomite, the presence of magnesium oxide and the tan color of aggregate fragments indicate that the aggregate particles represent fragments of burnt dolomite.

The XRD analysis reveals the presence of substantial amounts of MgO that remain unreacted in the tan color aggregate. Therefore, there is a real possibility of continued expansion and spalling of the precast concrete, unless the ingress of moisture is halted.

Despite the evidence of extensive cracking, discoloration and partial debonding, the coating on the exterior surface of the concrete has contributed to moisture being trapped behind the surface of the concrete.

The constant availability of moisture ensures that the expansion can and will continue as long as there are sites of unreacted lime (CaO) and magnesium oxide (MgO) in the tan color aggregate. Therefore, the existing surface coating should be removed by mechanical abrasion and replaced with a breathable coating such as a silane or siloxane sealer.

A Hüls Group Company

220 Davidson Avenue, Somerset, NJ 08873-6821 (800) 828-0919

Laboratory Report: TS-369-088

Page Two

SAMPLE PREPARATION:

Specimens received were oven dried at 110°C for 24 hours to remove atmospheric moisture. The entire circumference of each sample was waxed to prevent water absorption along sides during testing.

TREATMENT OF SAMPLE:

Specimen number 1 was laboratory treated with flood coat of Dynasylan BH-N. Specimen number 2 remained untreated as a control.

The third specimen was retained.

SIVENTO INC. STANDARD TEST PROCEDURES:

Water Absorption Test: (Modified ASTM C- 642)

The cooled specimen(s) was weighed to the nearest 0.01 grams, then placed treated or exposed surface only, in a tank containing several inches of tap water for a period of 24 hours. The specimen(s) was then removed from the water, towel dried and reweighed. The initial and final weights were used to calculate the 24 Hour Treated Water Absorption values.

Depth of Penetration:

Each sample was split longitudinally using a hammer and chisel. Sample half was placed fractured surface down in a water soluble dye solution. Only the untreated portion of each sample absorbs the solution and becomes stained. The depth of penetration is measured from the surface down to stained region, highest and lowest penetration is recorded.

Laboratory Report: TS-369-088

Page Three

TEST RESULTS:

Water Absorption and Depth of Penetration:

Sample No.	Sample Treatment	24 Hour Water Absorption (%)	Depth of Penetration (inches)
1	Dynasylan BH-N	0.27	Full
2	Control	0.9	—

CONCLUSION:

Test results indicate that Dynasylan BH-N is very effective at reducing water ingress in the supplied specimens. Data shows a very low 0.27 % uptake of water for the treated specimen compared to the relatively low 0.9 % for the control. Dynasylan BH-N penetrated the full depth of specimen to a measurement of approximately one inch.

Observations indicate that a significant amount of epoxy coating remains on the surface of the received samples.

Re: Kaiser Center- Mall Buildings Exterior Façade (Dolomite Panels) Feasibility Analysis

Dear Tomas,

Thank you for requesting Turner Construction Company to provide an analysis of the exterior façade of the two existing Mall Buildings at the Kaiser Center complex. Per your request, we have evaluated the feasibility of the intact salvaging (removal) of the Dolomite Precast Panels from the structure of the Mall Buildings, and then the potential preservation and reinstallation of these panels on a new structure at that location.

Scope

The scope of the study included a detailed review of the original 1958 Architectural and Structural Drawings and Specifications for both the Kaiser Center office tower and Mall Buildings prepared by Welton Becket & Associates, as well as a visual inspection of these buildings. Both the tower and Mall Buildings were reviewed due to the variation in panel thickness and attachment details given their different structural frames.

Findings

A review of the original construction documents for the Mall Buildings yielded two Architectural details and one Structural detail as the primary elements influencing our findings (please reference Architectural Detail "A" and Detail "B", and Structural Detail "C" attached to this document). The key element is the 1 inch thick grout layer shown between the 3 inch thick precast panels and the buildings' concrete frame, as referenced on the attached Details "A" and "B". The grout bonds the panel to the concrete as if the panel were cast in place, thus effectively creating a unified section. While the Structural details do not show how the panels are to be attached, Detail "C" does show the same unified section for the panel and grout of 4 inches thick. From our visual inspection we did not see anything to suggest that the panels were installed other than the manner is shown in the drawings. It should be noted that none of these details reference any mechanical attachment for the precast panels that is common in current construction methods (the fastener shown in Detail "A" is for a vertical aluminum mullion interfacing between the panels and is not for the panels' attachment to the building); please reference attached Details SK1A and SK1B as examples of typical precast attachment details.

It is important to note that in our experience renovating another high-rise building in Oakland of similar vintage with a similar precast system, the precast panels were actually used as the form surface for the shearwall concrete, thus casting the panels into the unified concrete frame. Separating the panels from the building's concrete frame required extensive hand demolition of the panels utilizing chipping guns. It is possible that this method of attachment may have been used in certain areas of the Mall Building as well, and thus removal would have the same result as the grouted bonding of the panels stipulated in the original design.

Conclusion

Based upon our review of the design documents and our visual inspection, the attachment of these precast Dolomite panels to the Mall Buildings' concrete frame precludes their mechanical removal other than by destructive methods. Further, even attempting to remove the panels by careful hand demolition would most likely cause them to disintegrate due to the nature of their material composition and age. Therefore, it is our opinion that, irrespective of cost, it would be infeasible for the Dolomite precast exterior façade at the Mall Buildings to be salvaged in a manner that would allow their reuse on any new structure. In addition, while it may be possible to salvage some limited amounts of the Dolomite material from the panels, a reasonable approach to demolition of the structure would not yield any "clean" or consistent material for incorporation into the proposed new building façade.

We also consulted two other construction firms that specialize in precast panel manufacturing and installation, Walters & Wolf and Clark Pacific, who reviewed and commented on the pertinent design documents with respect to the Dolomite panels and their opinions and conclusions align with ours.

We welcome the opportunity to discuss this analysis with you or whomever else you feel is appropriate, and would be glad to answer any further questions you may have.

Sincerely,

A handwritten signature in black ink that reads "Willy Mautner". The signature is stylized, with the first name "Willy" written in a cursive-like script and the last name "Mautner" in a more formal, blocky script.

Willy Mautner, AIA
Chief Estimator

*P3a. Description: (Describe resource and its major elements. Include design, materials, condition, alterations, size, setting, and boundaries.)
The Kaiser Center complex is on a large, irregularly shaped block bounded by 20th, Harrison, 21st, and Webster streets. The Kaiser Center complex consists of a twenty-eight-story Office Tower, the three-story and basement 20th Street Mall Building, the two-and-three-story Webster Street Mall Building, a three-and-four-story parking garage, and the Roof Garden on the top level parking garage. The Mall Buildings appear as a strong horizontal base that contrasts the verticality of the tower. The complex was designed by Welton Becket & Associates and completed in 1959. The roof garden was designed by the landscape architecture firm Osmundson & Staley and completed in 1960.

The office tower is made up of two basic components: a T-shaped tower with a straight stem and curved wings; and an asymmetrically located two-story podium supported by square piers at the first floor that extends beyond the plane of the T-shaped tower and follows the curve of the main façade. The main façade of the tower features fourteen bays separated by burnished aluminum piers. Each bay includes six windows surrounded by gold toned and natural aluminum frames. The side facades of the curved plane feature concrete panels with dolomite, a rock-like mineral product, aggregate. Other than the penthouse floor which features a higher ceiling height, all floors and bays on the main façade are identical. The straight vertical portion or stem of the tower features the same fenestration pattern as the main façade at the east and west façade and the same concrete panels with dolomite aggregate at the north and south façades. The north façade features signage reading, "Kaiser." The office tower has undergone few exterior alterations. The only interior alterations include an early-1990s renovation of the lobby and the conversion of the original cafeteria space into tenant space.

***Required information**

The parking garage is a three-and-four-story reinforced concrete rectangular plan building with a curved east façade that parallels the tower. The building is utilitarian and the only ornamentation present on the parking lot is a grid of narrow aluminum ribs and aluminum signage reading, "Kaiser Center Garage." The top level of the building is occupied by the Kaiser Center Roof Garden.

The 20th Street Mall building is a three-story and building located at the corner of 20th and Webster streets with a rectangular plan and flat roof. The building features oversize circular piers and glazed aluminum storefronts at the first floor giving the main mass of the building the appearance of floating. The first floor features stucco and white brick veneer cladding. The second floor has no fenestration but feature dolomite concrete panels with aluminum cantilevered canopies and vertical granite panels and aluminum fins above the entrances. The penthouse level occupies approximately three-quarters of the floor plate and is set back from the plane of the lower floors. The penthouse level features stucco cladding and closely arranged aluminum sash windows. The remainder of the penthouse level features an aluminum pergola. As of the date of this evaluation, a portion of this floor is vacant, but has traditionally been occupied by a restaurant that accesses the roof garden.

The Webster Street Mall building is a two-and-three-story building located at the corner of 21st and Webster streets with a rectangular plan and a flat roof covered by the roof garden. The first floor features stucco cladding and fixed full-height aluminum windows. The upper two floors feature slightly protruding dolomite concrete panels with no fenestration. Similar to the 20th Street Mall Building, the main mass of the building appears to float above the first floor.

The Kaiser Center Roof Garden is located on the top level of the parking garage at the northwest corner of the complex. The roof garden is rectangular in plan, except at the eastern edge, where the garden parallels the arc of the tower's main façade. The garden features curvilinear aggregate pathways, a series of irregularly-shaped undulating lawns, a circular lawn located in the center of the garden, low concrete curbing, specimen trees, shrub plantings, concrete benches and related site furnishings, and an 8,800 square foot reflecting pool. The pool features a wood bridge which was added between 1973 and 1975. A visual axis begins at the main entrance to the garden at the 20th Street Mall Building and runs through the reflecting pool and central circular lawn. A concrete HVAC building is located in the northwest corner of the garden. The building is approximately eighteen feet in height, clad in stucco and capped by a flat roof. The HVAC building is screened by specimen trees to alleviate the visual intrusion of this building within the garden.

The buildings and roof garden appear to be in excellent condition.

B2. Common name: Kaiser Center

B3. Original Use: Commercial, Garden

B4. Present use: Commercial, Garden

*B5. Architectural Style: Modern

*B6. Construction History: (Construction date, alterations, and date of alterations) The Kaiser Center buildings were constructed in 1959. The Roof Garden was completed in 1960. No major exterior alterations have been made. The Mall Buildings have undergone the most alterations, including changes to the storefronts, and cosmetic changes at the entrances (1960s and 1990s). The interior of the Mall buildings have been substantially altered due to tenant improvements. The cafeteria of the office tower was converted to office space (date unknown), and the lobby of the office tower was renovated in the early-1990s. The wood bridge, a later addition, was installed in the roof garden between 1973 and 1975.

(Discuss importance in terms of historical or architectural context as defined by theme, period, and geographic scope. Also address integrity)

The Kaiser Center Office Tower and Roof Garden is recognized as one of the symbols of Oakland. The 1960 Modern office complex with curved tower anchors the northwest corner of Lake Merritt in the heart of Oakland. Henry J. Kaiser, the magnate of the Kaiser Industries empire commissioned the iconic office complex to serve as the company's headquarters. Kaiser commissioned Welton Becket & Associates, an acclaimed commercial architecture firm, to design the new complex with office tower, retail buildings, parking garage, and roof garden. The complex is also significant for containing the first modern office tower constructed on the shores of Lake Merritt. The Roof Garden, at the top level of the parking garage, was designed by Osmundson & Staley, important landscape architects who created the largest contiguous roof garden in North America at the time of its completion. The roof garden is an important example of Bay Area Modern landscape architecture. Today the Kaiser Center complex stands as a tangible reminder of the importance of Oakland as an industrial and commercial center in the 1950s and 1960s, as an excellent example of the elegance of the Modern style, and the versatility of a master architect, Welton Becket & Associates.

***B10. Significance (cont.):**

Criterion 1 (Events)

The Kaiser Center appears to be eligible under Criterion 1 (Events) as a complex that reflects “events that have made a significant contribution to the broad patterns of local or regional history, or the cultural heritage of California or the United States.” In this case, the event is the influence of the Kaiser Industries on the history of California and the West Coast. As the only remaining headquarters building of Kaiser Industries, the multinational corporation that influenced the World War II war effort, infrastructure in California, and throughout the West Coast, and changed the health care industry, the Kaiser Center is a significant landmark testifying to an important industrial institution that helped Oakland remain a significant site of commercial and industrial activities in the post-War era.

The complex is also significant as a reminder of the movement of Oakland's Downtown commercial core toward Grand Avenue and Lake Merritt. The Kaiser Center led the shift of the commercial core from 14th and Broadway in downtown Oakland to Lake Merritt. While earlier residential towers such as the Lake Merritt Hotel (1927) and the Bellevue-Staten Building (1929) had been present on the lake, the Kaiser Center was the first true modern commercial skyscraper complex to be located on Lake Merritt. Other modern office towers followed the shift away from downtown including the Ordway Building (1970), the twenty-seven-story Lake Merritt Plaza (1985) at 1999 Harrison Street, and a number of skyscraper office buildings dating from the 1970s to the 1990s are located on prominent intersections in the immediate area.

Criterion 2 (Persons)

The Kaiser Center appears eligible for the California Register under Criterion 2 (Persons) for its association with Henry J. Kaiser. Kaiser is significant as an innovative industrialist with a larger than life personality who built more ships than any other builder during World War II, completed massive construction projects like the Hoover Dam, headed the first company to manufacture steel on the West Coast, and developed a health care organization for workers that became a model for Health Maintenance Organizations (HMOs) across the country. Kaiser was influential in the design of the Kaiser Center; purportedly telling the management team and the architects to “double it” when asked his opinion of the proposed size of the building. Kaiser is also frequently credited for the creation of the roof garden. Additionally, Kaiser held his offices, where he oversaw his multitude of companies and had an apartment at the 27th floor of the building. While many of Kaiser's industrial buildings still exist, the Kaiser Center in Oakland is the only remaining corporate headquarters connected to Kaiser Industries. Kaiser's earlier Oakland headquarters building, at 1924 Broadway, was demolished in the 1990s and therefore the Kaiser Center is an important building that expresses the importance of Oakland as the world headquarters of Kaiser Industries.

Criterion 3 (Architecture)

The Kaiser Center appears eligible for the California Register under Criterion 3 for embodying the distinctive characteristics of the Modern style. The Kaiser Center is a well-preserved example of the style as applied to a corporate headquarters complex. Characteristic features of the complex include its variety of building types: office tower, retail wings, and parking garage all designed in a compatible style; its site in a landscaped plaza with views to Lake Merritt. The complex appears as a strong horizontal base that is contrasted by a vertical office tower. The office tower features structural piers elevating the building's mass above the plaza, a mezzanine podium at the base, a T-shaped plan, a sweeping curved façade, flat roof, polychrome aluminum and glazed wall surfaces, aggregate concrete panels at secondary facades, and standardized bays with little variation. The Mall Buildings are completed in the same style and feature rectangular plans, flat roofs, structural piers elevating the building's mass above the first floor, and dolomite panel cladding. The materials used throughout the complex were selected to showcase the variety of Kaiser manufactured materials including aluminum and dolomite.

The Kaiser Center is also important as a designed office and retail complex, with an office tower, retail, landscaped open space, and parking incorporated on one site. Kaiser's headquarters was not envisioned as solely an office building, but as a group of associated buildings and landscapes that were intended to be used by both Kaiser Industries employees and Oakland community members.

In addition to being an example of a type, the Kaiser Center is also significant as the work of a master, Welton Becket & Associates. Welton Becket & Associates was an important modernist architecture firm working throughout the United States. The firm specialized in corporate headquarters, hotels, and cultural centers and was the largest architecture firm in the United States in the 1950s. The Kaiser Center is an excellent example of Welton Becket's work for corporate clients, who relied upon the firm to embody the corporation's philosophy in physical form. Welton Becket's design for the Kaiser Center showcases not only the materials produced by Kaiser Industries but also the characteristics Kaiser Industries were known for: innovation, in the use of a curved façade; and concern for employee well-being embodied in the inclusion of a roof garden.

The roof garden is significant for its design and as the largest contiguous roof garden in North America at the time of its construction. The garden features many of the hallmarks of modern landscape design including undulating topography, curvilinear pathways, geometrically shaped lawns, simple materials such as concrete pathways, planters, and benches; (continued)

***B10. Significance (cont.):**

trimmed hedges, shrubs, specimen trees, and an asymmetrical pool. The design by Osmundson & Staley is indicative of the Bay Area Modern landscape architecture popularized by designers such as Thomas Church, Robert Royston, and Lawrence Halprin. The Kaiser Center roof garden by Osmundson & Staley exemplifies the mid-century California Style first popularized by Church and his contemporaries in the 1940s. The California Style emphasized the importance of indoor/outdoor living and relied heavily on a modern landscape architectural vocabulary to achieve this effect. The decision to include a roof garden as part of the Kaiser Center complex marked an important recognition of the potential of the roof garden to create a more healthful and attractive office environment within the city.

Criterion 4 (Information Potential)

This property was not fully assessed for its potential to yield information important in prehistory or history, per California Register Criterion 4 (Information Potential).

The Kaiser Center complex retains its integrity, and the only significant alterations to public spaces include the renovation of the lobby and replacement of the cafeteria by tenant space. The exterior of the complex has seen few alterations, other than storefront alterations, signage changes, and the installation of ornament at the Mall Building entrances. The roof garden also retains integrity and though many of the plantings have been replaced over time, the new plantings are consistent with the original design. Overall, the complex retains sufficient integrity to convey its historical significance.

CONC. FINISHING SCHEDULE

- 1. Cement plaster, sand-finish all vertical surfaces with 1/2" - 3/4" sand. Cement sand-finish over mesh concrete of 1/2" diameter. Minimum thickness 1/2" unless specified.
- 2. Applied aggregate concrete w/ 1/2" - 3/4" Cement Sand-finish. Cement sand-finish over mesh concrete of 1/2" diameter. Minimum thickness 1/2" unless specified.
- 3. Applied aggregate concrete with white Portland cement. Cement sand-finish over mesh concrete of 1/2" diameter. Minimum thickness 1/2" unless specified.
- 4. Bridge finish - see detail 10.

LEGEND

- specimen tree location
- roof support
- roof drain
- planting
- detail number
- sheet number
- path - see 10
- also 10 - see the schedule this sheet

GENERAL NOTES

All concrete shall be lightweight concrete. See specifications.

See finishing schedule on this sheet for color & texture.

Typical existing elevations are as follows: 50' - 52' @ roof drains, 50' - 52' @ column locations where roof drain does not occur exceptions as noted on plan.

Contractor to pour 3 square samples each of concrete (A, B, C, D) (see 10, 11, 12) on site, to be approved by Landscape Architect as standard of quality for all subsequent work. All work not equal to samples in quality shall be removed and replaced @ no extra cost to the owner. Samples shall be removed from site by contractor when all pours have been completed and approved by the L.A.

Max. allowable roof loads are as follows: 125 lbs. per sq. ft. for 18,000 lbs. total weight of roof & columns with the following exceptions: Area A - 90 lbs. per sq. ft., Area B - 125 lbs. per sq. ft. no concentrated loads allowed. Contractor shall observe these limitations in carrying out his work.

SCHEDULE OF DRAWINGS

- L-1 key map, conc. finishing schedule, general notes, plot plan-parking garage roof
- L-2 grading plan - parking garage roof (1/2" supplementary grading plan)
- L-3 staking plan
- L-4 areas shown @ 1/2" scale - details
- L-5 planting plan - parking garage roof
- L-6 irrigation plan
- L-7
- L-8
- L-9
- L-10 details
- S-1 bridge details
- E-1 electrical plan
- E-2 electrical details
- ME-1 reflection pool

NOTE:

Note relative elevations of roofs & ground level as given in site plan above.

Re: Three proposed cultural resource studies in Alameda County
Kaiser Center Oakland Redevelopment Project, Oakland (ESA Project #D206213)
Children's Hospital and Research Center Replacement Project, Oakland (ESA Project # 207558)
Sutter Medical Center, Castro Valley (ESA Project #207766)

Dear Ms. Kehl:

Environmental Science Associates (ESA) is conducting cultural resources study for three projects in Alameda County. The Kaiser Center Oakland Redevelopment Project is located in downtown Oakland and consists of the removal of existing buildings and construction of two 42- and 34-story towers. The Children's Hospital and Research Center Replacement Project is also in Oakland and consists of the construction of a new 12-story hospital tower, a new central utility plant and parking structure. The Sutter Medical Center Project is located further south in Castro Valley and includes the demolition of an existing 8-story hospital and the construction of a new 6-story hospital and medical office (see attached maps).

In an effort to address any potential impact to archaeological or ethnographic resources, we are seeking comments from Native American representatives; your name was supplied to us by the Native American Heritage Commission as a contact for this area. We would appreciate your comments identifying any concerns or issues pertinent to this project.

Thank you for your cooperation on this matter. If you have any questions, please contact me at 707/795-0920.

Sincerely,

A handwritten signature in black ink that reads "Heidi Koenig". The signature is fluid and cursive, with the first name "Heidi" and last name "Koenig" clearly distinguishable.

Re: Proposed: Kaiser Center Oakland Redevelopment project. Childrens Hospital and Research Center Replacement project. Sutter Medical Center, Castro Valley. All projects in Alameda County.

Dear Ms. Koenig:

A record search of the sacred land file has failed to indicate the presence of Native American cultural resources in the immediate project area. The absence of specific site information in the sacred lands file does not indicate the absence of cultural resources in any project area. Other sources of cultural resources should also be contacted for information regarding known and recorded sites.

Enclosed is a list of Native Americans individuals/organizations who may have knowledge of cultural resources in the project area. The Commission makes no recommendation or preference of a single individual, or group over another. This list should provide a starting place in locating areas of potential adverse impact within the proposed project area. I suggest you contact all of those indicated, if they cannot supply information, they might recommend others with specific knowledge. By contacting all those listed, your organization will be better able to respond to claims of failure to consult with the appropriate tribe or group. If a response has not been received within two weeks of notification, the Commission requests that you follow-up with a telephone call to ensure that the project information has been received.

If you receive notification of change of addresses and phone numbers from any of these individuals or groups, please notify me. With your assistance we are able to assure that our lists contain current information. If you have any questions or need additional information, please contact me at (916) 653-4038.

Sincerely,

Debbie Pilas-Treadway

Re: Kaiser Center- Mall Buildings Exterior Façade (Dolomite Panels) Feasibility Analysis

Dear Tomas,

Thank you for requesting Turner Construction Company to provide an analysis of the exterior façade of the two existing Mall Buildings at the Kaiser Center complex. Per your request, we have evaluated the feasibility of the intact salvaging (removal) of the Dolomite Precast Panels from the structure of the Mall Buildings, and then the potential preservation and reinstallation of these panels on a new structure at that location.

Scope

The scope of the study included a detailed review of the original 1958 Architectural and Structural Drawings and Specifications for both the Kaiser Center office tower and Mall Buildings prepared by Welton Becket & Associates, as well as a visual inspection of these buildings. Both the tower and Mall Buildings were reviewed due to the variation in panel thickness and attachment details given their different structural frames.

Findings

A review of the original construction documents for the Mall Buildings yielded two Architectural details and one Structural detail as the primary elements influencing our findings (please reference Architectural Detail "A" and Detail "B", and Structural Detail "C" attached to this document). The key element is the 1 inch thick grout layer shown between the 3 inch thick precast panels and the buildings' concrete frame, as referenced on the attached Details "A" and "B". The grout bonds the panel to the concrete as if the panel were cast in place, thus effectively creating a unified section. While the Structural details do not show how the panels are to be attached, Detail "C" does show the same unified section for the panel and grout of 4 inches thick. From our visual inspection we did not see anything to suggest that the panels were installed other than the manner is shown in the drawings. It should be noted that none of these details reference any mechanical attachment for the precast panels that is common in current construction methods (the fastener shown in Detail "A" is for a vertical aluminum mullion interfacing between the panels and is not for the panels' attachment to the building); please reference attached Details SK1A and SK1B as examples of typical precast attachment details.

It is important to note that in our experience renovating another high-rise building in Oakland of similar vintage with a similar precast system, the precast panels were actually used as the form surface for the shearwall concrete, thus casting the panels into the unified concrete frame. Separating the panels from the building's concrete frame required extensive hand demolition of the panels utilizing chipping guns. It is possible that this method of attachment may have been used in certain areas of the Mall Building as well, and thus removal would have the same result as the grouted bonding of the panels stipulated in the original design.

**Conclusion**

Based upon our review of the design documents and our visual inspection, the attachment of these precast Dolomite panels to the Mall Buildings' concrete frame precludes their mechanical removal other than by destructive methods. Further, even attempting to remove the panels by careful hand demolition would most likely cause them to disintegrate due to the nature of their material composition and age. Therefore, it is our opinion that, irrespective of cost, it would be infeasible for the Dolomite precast exterior façade at the Mall Buildings to be salvaged in a manner that would allow their reuse on any new structure. In addition, while it may be possible to salvage some limited amounts of the Dolomite material from the panels, a reasonable approach to demolition of the structure would not yield any "clean" or consistent material for incorporation into the proposed new building façade.

We also consulted two other construction firms that specialize in precast panel manufacturing and installation, Walters & Wolf and Clark Pacific, who reviewed and commented on the pertinent design documents with respect to the Dolomite panels and their opinions and conclusions align with ours.

We welcome the opportunity to discuss this analysis with you or whomever else you feel is appropriate, and would be glad to answer any further questions you may have.

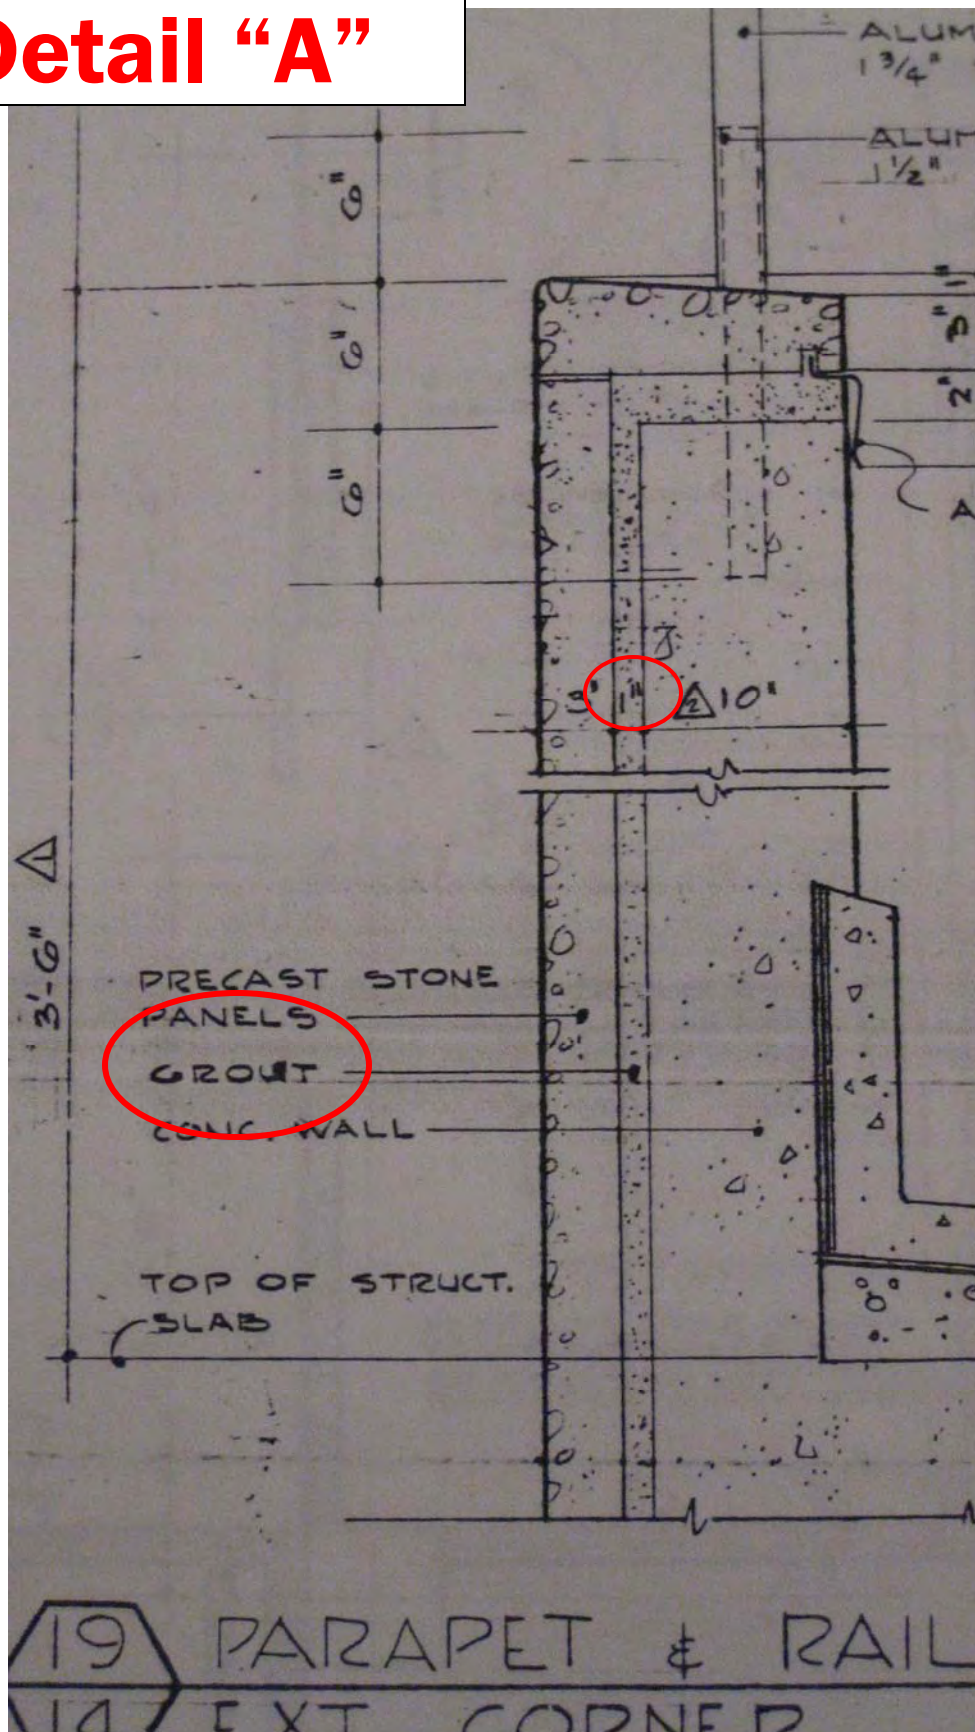

Sincerely,

A handwritten signature in black ink that reads "Willy Mautner". The signature is stylized, with the first name "Willy" written in a cursive-like script and the last name "Mautner" in a more formal, blocky script.
